General Information

- Two categories: Head (iceberg) and leaf
- Lettuce is third-most consumed vegetable in United States
- Americans consume more than 14 pounds of head lettuce and 10 pounds of leaf lettuce per capita annually

Foodborne Illness Outbreaks

Microbial contamination of leafy green vegetables, including lettuce, is attributed to 22% of foodborne illness outbreaks in the United States annually. Lettuce has been responsible for a number of recent large foodborne illness outbreaks, including a 2013 case in Arizona which caused 59 illnesses. In 2010, 114 consumers in Illinois were sickened by *Salmonella* after consuming lettuce. Table 1 shows notable foodborne illness outbreaks attributed to lettuce since 2010:

Storage and Cooling Conditions

Lettuce is best maintained as close to 0°C as possible. Because of lettuce’s large water content, a high humidity level is preferable. Lettuce is highly sensitive to ethylene and will decay if not isolated from high ethylene-producing produce in storage. Figure 2 indicates ideal storage conditions:

<table>
<thead>
<tr>
<th>Produce</th>
<th>Optimal Storage Temp., °C</th>

Good Agriculture Practices (FDA, 2006)

- Develop and implement procedures for preventing pest infestation in irrigation pipe and drip tape.
- Ensure that water used in all pre- and post- harvest applications meets microbial water standards. This includes water used for hydrovac cooling.
- Any cooling equipment used on lettuce should be cleaned and sanitized regularly.
- Never use raw animal manure on or near lettuce.
- Chlorine is insufficient to kill pathogens in lettuce latex after cutting and coring. A stronger FDA-approved sanitizing agent should be used.

Pathogenic Behavior in Commodity

Typical cleaning practices are incapable of completely eliminating bacteria from surface-contaminated produce. The only way to eliminate contamination is to prevent pathogens from coming into contact with lettuce during the entire farm-to-fork process. Pathogens can easily be splashed onto plants from soil or transferred by human or animal contact. Dried manure can also be wind-blown onto plants, and Salmonella has been shown to be resistant to drying. Noroviruses are another concern for lettuce. Noroviruses are the most common foodborne disease and are often found in lettuce.

Norovirus is significantly smaller than bacteria, and has been shown to be capable of transferring up into the lettuce plant from the roots.
